-- What is the difference between SQL and NoSQL databases?

1. Data Model

SQL: Uses tables (rows and columns) with a fixed schema.

NoSQL: Uses flexible models like documents (JSON), key-value pairs, graphs, or wide-column stores.

2. Schema

SQL: Requires a predefined schema (structure must be declared before inserting data).

NoSQL: Schema-less (fields can be added on the fly, and each record can have different fields).

3. Query Language

SQL: Uses SQL (Structured Query Language) for querying and managing data.

NoSQL: Uses database-specific query languages (e.g., MongoDB uses BSON queries, Cassandra uses CQL).

4. Relationships

SQL: Supports relationships between tables (e.g., foreign keys, joins).

NoSQL: No built-in relationships; data is often denormalized (all related data is stored together).

What is the difference between SQL and NoSQL databases?

Here's a concise summary of the **core differences** between SQL and NoSQL databases:

1. Data Model

- **SQL:** Uses **tables** (rows and columns) with a **fixed schema**.
- **NoSQL:** Uses **flexible models** like documents (JSON), key-value pairs, graphs, or wide-column stores.

2. Schema

- **SQL:** Requires a **predefined schema** (structure must be declared before inserting data).
- **NoSQL:** **Schema-less** (fields can be added on the fly, and each record can have different fields).

3. Query Language

- **SQL:** Uses **SQL (Structured Query Language)** for querying and managing data.
- **NoSQL:** Uses **database-specific query languages** (e.g., MongoDB uses BSON queries, Cassandra uses CQL).

4. Relationships

- **SQL:** Supports **relationships** between tables (e.g., foreign keys, joins).
- **NoSQL:** **No built-in relationships:** data is often **denormalized** (all related data is stored

-- Write a Python function to check if a string is a palindrome.

def is_palindrome(text: str) -> bool:

"""Return True if text reads the same forwards and backwards."""

return text == text[

Write a Python function to check if a string is a palindrome.

python

Collapse

Copy

```
def is_palindrome(text: str) -> bool:
    """Return True if text reads the same forwards and backwards."""
    return text == text[::-1]
```

Example:

python

Collapse

Copy

```
print(is_palindrome("racecar")) # True
print(is_palindrome("hello"))  # False
```
